Measure Theory Third Week

## Theorem (1.4.10):

Let $A$ be a Lebesgue measurable subset of $\mathbf{R}$ such that $\lambda(A)>0$.

The set diff $(A):=\{x-y \mid x, y \in A\}$ contains an open interval containing 0 .

Proof: Without loss of generality, we can assume that $A$ is compact.

With $\lambda(A)=r>0$,
there is an open set $B$ such that $B$ contains $A$ and $\lambda(B)<(1+\epsilon) r$. for any $\epsilon>0$.

We require that $\epsilon$ be less than 1 .
As $\mathbf{R} \backslash B$ is a closed, disjoint from $A$ and thus has a positive distance $d$ to $A$, $A+\delta$ is contained in $B$ for all $\delta$ satisfying $|\delta|<d$.

But if there were no overlap between the sets $A$ and $A+\delta$ for $\delta<d$,
then $A \cup(A+\delta)$ would be a Lebesgue measurable set of measure $2 r$ inside of $B$, which is impossible since $\lambda(B)<(1+\epsilon) r$.

So for any given $\delta$ with $|\delta|<d$ there is an $a \in A \cap A+\delta$,
meaning that $a=a^{\prime}+\delta$ for some other $a^{\prime} \in A$ and $\delta=a-a^{\prime}$.

We see that for every $\epsilon$ there is a $d$ such that all but an $\epsilon$ fraction of the set $A$ is used to get the difference set to include $(-d, d)$.

Theorem (1.4.11): There is a partition of $\mathbf{R}$ into two parts $A, B$,
meaning $A \cap B=\emptyset$ and $A \cup B=\mathbf{R}$,
such that for every finite interval $I$ :
$\lambda^{*}(A \cap I)=\lambda^{*}(B \cap I)=\lambda^{*}(I)$ and
every Lebesgue measurable subset $C$ either contained in $A$ or $B$ has measure zero.

Note: The natural idea, a homomorphism from $\mathbf{R}$ to $\mathbf{Z}_{2}$ and letting $A=\phi^{-1}(0)$ and $B=\phi^{-1}(1)$, is not possible.

Whenever $\phi(r)=1$ then what should be $\phi\left(\frac{r}{2}\right)$ ?

## Proof:

Let $W=\mathbf{Q}+\mathbf{Z} \sqrt{2}$,
$\phi: W \rightarrow \mathbf{Z}_{2}$ is defined by
$\phi\left(\frac{a}{b}+n \sqrt{2}\right)=n(\bmod 2)$.
Because $\sqrt{2}$ is irrational, $\phi$ is well defined and a homomorphism.

Also both $G_{0}:=\phi^{-1}(0) \subset W$ and $G_{1}:=$ $\phi^{-1}(1) \subset W$ are dense in $\mathbf{R}$.

Define an equivalence relation $\sim$ by $r \sim s$ if and only if $r-s \in W$.

Let $E$ be a set such that $|E \cap B|=1$ for every equivalence class $B$.

For every $r \in \mathbf{R}, \quad r=e+\frac{a}{b}+n \sqrt{2}$,
for some $e \in E, a, b \in \mathbf{Z}, n \in \mathbf{Z}$.
$A$ is the subset where $n$ is even and $B$ is the subset where $n$ is odd.
$A$ and $B$ are well defined because $r$ cannot equal $e^{\prime}+\frac{a^{\prime}}{b^{\prime}}+n^{\prime} \sqrt{2}$ for any other choices, as then $e$ and $e^{\prime}$ would belong to the same equivalence class.

# Assume that either $A$ or $B$ contained a Lebesgue measurable set of positive measure. 

Either $A-A$ or $B-B$ must contain some member of the dense set $G_{1}$, or
$\frac{a_{0}}{b_{0}}+n_{0} \sqrt{2}=e_{1}+\frac{a_{1}}{b_{1}}+n_{1} \sqrt{2}-e_{2}-\frac{a_{2}}{b_{2}}+n_{2} \sqrt{2}$ with $n_{0}$ odd, both $n_{1}$ and $n_{2}$ either even or odd, and $e_{1}, e_{2} \in E$.

As $e_{1}$ and $e_{2}$ cannot be distinct (otherwise they would represent the same equivalence relation), $n_{0}=n_{1}+n_{2}$ would be a contradiction.

Now suppose that either $A \cap I$ or $B \cap I$ has an outer Lebesgue measure less than $I$ for some finite interval $I$.

That means $A \cap I$ or $B \cap I$ can be covered by some open set of measure strictly less than $I$.
implying that either $I \backslash A=I \cap B$ or $I \backslash B=$ $I \cap A$ contains a closed set of positive measure, which neither does.

A measure $\mu$ of a measure space $(X, \mathcal{A}, \mu)$ is complete
if $A \in \mathcal{A}, \mu(A)=0$ and $B \subseteq A$ imply that $B \in \mathcal{A}$.

With $(X, \mathcal{A}, \mu)$ a measure space,
the completion $\mathcal{A}_{\mu}$ is the collection of subsets $A$
for which there are sets $E, F \in \mathcal{A}$
with $E \subseteq A \subseteq F$ and $\mu(F \backslash E)=0$.

The completion $\bar{\mu}$ is the measure defined on $\mathcal{A}_{\mu}$
such that $\bar{\mu}(A)=\mu(E)=\mu(F)$.

This is well defined as there cannot be two such levels.

Lemma (1.5.1): Let $(X, \mathcal{A}, \mu)$ be a measure space.
$\mathcal{A}_{\mu}$ is a $\sigma$-algebra on $X$ that includes $\mathcal{A}$ and $\bar{\mu}$ is a measure defined on $\mathcal{A}_{\mu}$ that is complete.

Proof: Containment of $\mathcal{A}$ in $\mathcal{A}_{\mu}$ and closure by complementation are trivial.

If $A_{1}, A_{2}, \ldots$ is a sequence of sets in $\mathcal{A}_{\mu}$ and $E_{i}$ and $F_{i}$ are sequences in $\mathcal{A}$ with $\forall i \quad E_{i} \subseteq A_{i} \subseteq F_{i}$ and $\mu\left(F_{i} \backslash E_{i}\right)=0$ then by countable additivity
$0=\sum_{i=1}^{\infty} \mu\left(F_{i} \backslash E_{i}\right) \geq \mu\left(\cup_{i=1}^{\infty}\left(F_{i} \backslash E_{i}\right)\right) \geq$ $\mu\left(\cup_{i=1}^{\infty} F_{i} \backslash \cup_{i=1}^{\infty} E_{i}\right) \geq 0$.

And if the $A_{1}, A_{2}, \ldots$ are disjoint the same pairs $E_{i}$ and $F_{i}$ of sequences show that
$\sum_{i=1}^{\infty} \mu\left(F_{i}\right)=\sum_{i=1}^{\infty} \mu\left(E_{i}\right) \leq \bar{\mu}\left(\cup_{i=1}^{\infty} A_{i}\right) \leq$
$\sum_{i=1}^{\infty} \mu\left(F_{i}\right)$,
hence equality.

Let $(X, \mathcal{A}, \mu)$ be a measure space, and $A$ any subset of $X$.
$\mu^{*}(A)=\inf \{\mu(B) \mid A \subseteq B, B \in \mathcal{A}\}$ and $\mu_{*}(A)=\sup \{\mu(B) \mid A \supseteq B, B \in \mathcal{A}\}$.

Lemma: $\mu^{*}$ is an outer measure.

Proof: $\mu^{*}(\emptyset)=0$ and monotonicity are trivial.

Let $A_{1}, A_{2}, \ldots$ be a sequence of sets.

Suppose that $\sum_{i=1}^{\infty} \mu^{*}\left(A_{i}\right)<\infty$ :

For every $i=1,2, \ldots$ let $B_{i}$ be a set in $\mathcal{A}$ containing $A_{i}$ such that $\mu\left(B_{i}\right) \leq \mu^{*}\left(A_{i}\right)+\frac{\epsilon}{2^{i}}$.
$B=\cup_{i=1}^{\infty} B_{i}$ includes $A=\cup_{i=1}^{\infty} A_{i}$ and
$\sum_{i=1}^{\infty} \mu^{*}\left(A_{i}\right) \geq \sum_{i=1}^{\infty} \mu\left(B_{i}\right)-\epsilon \geq \mu(B)-$ $\epsilon \geq \mu^{*}(A)-\epsilon$.

Lemma (1.5.5) Given that $\mu^{*}(A)<\infty$, $A$ belongs to $\mathcal{A}_{\mu}$ if and only if $\mu_{*}(A)=$ $\mu^{*}(A)$.

If $A$ belongs to $\mathcal{A}_{\mu}$ then there are sets $E, F \in$ $\mathcal{A}$ such that $E \subseteq A \subseteq F$ and $\mu(F \backslash E)=0$.

From $\mu(E) \leq \mu_{*}(A) \leq \mu^{*}(A) \leq \mu(F)$
all are equal.

On the other hand, if $\mu_{*}(E)=\mu^{*}(E)<\infty$ there are sequences of sets $A_{1}, A_{2}, \ldots$ and $B_{1}, B_{2}, \ldots$
with $A_{i} \subseteq E$ and $E \subseteq B_{i}$ and $\mu\left(A_{i}\right) \geq \mu_{*}(E)-\frac{1}{2^{i}}$ and $\mu^{*}(E)+\frac{1}{2^{i}} \geq \mu\left(B_{i}\right)$.

The sets $A=\cup_{i}^{\infty} A_{i}$ and $B=\cap_{i}^{\infty} B_{i}$
are both in $\mathcal{A}$ and have the same common measure size $\mu^{*}(E)=\mu_{*}(E)$.
